## ABSTRACT

The demand for corn is increasing in Asia for feed and biofuel. It is grown in the rice-corn cropping system. During harvest of corn, however, seeds drop on the soil surface and become problems as volunteer corn seedlings in the subsequent dry-seeded rice crop, in which the suppressive effect of standing water is absent. A study was conducted in screenhouse and field conditions to evaluate the effect of rice herbicides on the management of volunteer corn seedlings. In the screenhouse experiment, bispyribac-sodium at 0.030 and 0.045 kg·ai·ha<sup>-1</sup> provided complete control of corn seedlings. Fenoxaprop + ethoxysulfuron and penoxsulam + cyhalofop did not provide effective control of corn seedlings. In the field, the sole application of bispyribac and sequential application of oxadiazon and bispyribac suppressed corn biomass by 60% - 82% and 89% - 91%, respectively, as compared with the nontreated control. The results of this study demonstrate that, in the absence of other management strategies, volunteer corn seedlings in dry-seeded rice systems can be managed by using bispyribac-sodium.

**Keywords:** Volunteer Corn; Asia; Bispyribac; Seeded Rice

## 1. Introduction

Double- and triple-crop rice monoculture systems are common in tropical humid and subtropical Asia. These intensive rice production systems provide staple food for hundreds of millions of people, and they greatly affect the livelihoods of the urban and rural poor people in Asia. Recently, however, increasing demand for corn in many Asian countries has resulted in the diversification of rice monoculture systems to rice-corn cropping systems. Corn is also more water efficient than rice, especially in the wake of increasing water scarcity [1]. The rice-corn cropping system is gaining importance mainly because of increasing demand of corn for feed and biofuel [2]. Corn is grown on around 2.6 Mha in the Philippines, where it is cultivated in dry seasons.

Growing corn in the dry season and rice in the wet season can provide high total productivity in the rice-corn cropping system. In the Philippines, glyphosate-resistant corn cultivars are grown [3]. In these corn cultivars, glyphosate (a nonselective herbicide) is applied as post-

emergence, which provides very effective weed control. During harvest, a huge amount of corn seeds drop in the field, especially where corn is harvested using machines. These corn seeds germinate and emerge in the subsequent rice crop. These volunteer corn seedlings severely compete with rice crop.

In traditional puddled-transplanted rice systems, it is easy to manage volunteer corn seedlings with the use of intensive tillage in wet conditions and flooding. Because of labor and water scarcity, traditional rice systems are being replaced by mechanical-sown dry-seeded rice systems [4,5]. In these systems, the suppressive effect of standing water is absent. In addition, the conditions are suitable for corn germination in dry-seeded systems.

Because of intensification and diversification, there is no sufficient time to manage volunteer corn seedlings before crop planting. In such situations, there is a need to find suitable control measures for volunteer corn in dry-seeded rice systems. A computer search revealed no information on the control of corn in rice. Some herbicides may be phytotoxic to corn but not to rice. However, such information is not available in the literature, especially in

\*Corresponding author.

the rice-corn cropping system. Therefore, a study was conducted in controlled and field conditions to evaluate the effect of rice herbicides on volunteer corn seedlings.

## 2. Materials and Methods

Two experiments were conducted to evaluate the efficacy of different herbicides on volunteer corn seedlings. The first experiment was conducted in pots in a greenhouse and the second experiment was conducted in a field at the International Rice Research Institute, Los Baños, Philippines.

### 2.1. Greenhouse Experiment

Six plants of rice (cv. Rc222) and corn (cv P3482YR) were grown in plastic pots (30 cm diameter and 27 cm height). Rice and corn plants were grown alternatively in the same pot. The pots were filled with 9 kg soil. The soil was collected from upland rice fields and it had clay, sand, and silt contents of 40%, 22%, and 38%, respectively. Rice and corn were planted on August 28, 2012. There were seven treatments; nontreated control, bispyribac-sodium (bispyribac, hereafter) applied at 0.030 and 0.045 kg·ai·ha<sup>-1</sup> at 10 days after planting (DAP), fenoxaprop-ethyl + ethoxysulfuron applied at 0.045 and 0.068 kg·ai·ha<sup>-1</sup> at 15 DAP, and penoxsulam + cyhalofop applied at 0.072 and 0.108 kg·ai·ha<sup>-1</sup> at 15 DAP. Herbicides were sprayed using a research track sprayer that delivered 210 L ha<sup>-1</sup> spray solution through flat-fan nozzles.

In the greenhouse, the pots were laid out in a complete block design. There were eight replications for each treatment. Plant samples were harvested 30 DAP. Seedling survival percent, plant height, and aboveground shoot biomass were measured for both rice and corn. For biomass, plant samples were placed in an oven at 70°C for 72 hours.

### 2.2. Field Experiment

A field experiment was conducted in a randomized complete block design and there were three replications of each treatment. This experiment was conducted two times (and therefore, a total of six replications). The experimental site was rotovated twice using a 4-wheel tractor before crop planting and then it was leveled using a wooden board.

Before crop planting, corn (cv. P3482YR) seeds were broadcast uniformly at a rate of 50 seeds m<sup>-2</sup>. These corn seeds were collected from the crop (glyphosate-resistant) grown on the farm. Rice (cv. Rc222) was planted by hand at 100 kg·ha<sup>-1</sup> in 20 cm wide rows. The crop was planted on January 23, 2013 (for first experiment) and March 20, 2013 (for second experiment). Immediately after planting, a light irrigation was given and then irri-

gated as required by the crop. Nitrogen (N) was applied in two equivalent splits (30 kg·N·ha<sup>-1</sup>) at 14 and 28 DAP.

There were eight weed control treatments: weed-free (no corn was broadcast in this treatment); weedy (nontreated control); butachlor + propanil at 0.60 kg·ai·ha<sup>-1</sup> at 6 DAP; oxadiazon at 0.75 kg·ai·ha<sup>-1</sup> at 1 DAP; bispyribac at 0.030 and 0.045 kg·ai·ha<sup>-1</sup> at 14 DAP, oxadiazon at 0.75 kg·ai·ha<sup>-1</sup> at 1 DAP followed by bispyribac at 0.030 kg·ai·ha<sup>-1</sup> at 14 DAP; and oxadiazon at 0.75 kg·ai·ha<sup>-1</sup> at 1 DAP followed by bispyribac at 0.045 kg ai ha<sup>-1</sup> at 14 DAP. Herbicides were applied with a knapsack sprayer that delivered 320 L·ha<sup>-1</sup> of spray solution through flat-fan nozzles.

At 35 DAP, rice and corn plants were sampled from a central 1-m<sup>2</sup> area. For rice, leaf area and aboveground biomass were measured. For corn, plant density and biomass were measured. Biomass was measured after oven drying samples at 70°C for 72 hours.

### 2.3. Statistical Analyses

Data from greenhouse and field experiments were analyzed with analysis of variance (ANOVA) to evaluate differences between treatments and the means were separated by least significant difference (LSD) at the 5% level of significance [6].

## 3. Results and Discussion

### 3.1. Greenhouse Experiment

In the pot study, herbicide application did not influence seedling survival of rice (**Table 1**). These results suggest that the tested herbicides can be used on rice. In fact, these herbicides are being used in dry-seeded rice to manage broad-spectrum of weed flora [7,8]. Tallest rice plants were observed in the nontreated control (**Table 1**). In the nontreated control, rice plants grew with corn plants and the stiff competition might have resulted in tallest rice plants in this treatment. All herbicides suppressed the height of rice plants. Bispyribac is known to cause stunting in rice [9]. However, its tolerance is dependent on rice cultivar [10,11].

Bispyribac application at both rates provided complete control of corn (**Table 1**). The next best treatment was fenoxaprop + ethoxysulfuron at both doses (19% - 25% survival). After the application of penoxsulam + cyhalofop, 50% - 70% corn seedlings survived. Similar response was observed for corn height. In the nontreated control, corn produced highest biomass (2.7 g·plant<sup>-1</sup>). Bispyribac application killed all corn plants and therefore no biomass was observed. Although corn produced higher biomass in the penoxsulam + cyhalofop treatment (0.64 - 0.67 g·plant<sup>-1</sup>) compared to fenoxaprop + ethoxysulfuron treatment (0.36 - 0.39 g·plant<sup>-1</sup>), the difference

**Table 1. Effect of herbicides on the survival, height, and biomass of rice and corn seedlings.**

Treatments	Rice			Corn		
	Survival	Height	Biomass	Survival	Height	Biomass
	(%)	(cm·plant <sup>-1</sup> )	(g·plant <sup>-1</sup> )	(%)	(cm·plant <sup>-1</sup> )	(g·plant <sup>-1</sup> )
Control	100	38.2	0.149	100	81.6	2.71
Bispyribac 0.030	100	27.1	0.114	0	0	0
Bispyribac 0.045	94	30.4	0.165	0	0	0
Fenoxaprop + ethoxysulfuron 0.045	98	33.6	0.210	25	24.5	0.36
Fenoxaprop + ethoxysulfuron 0.068	100	25.5	0.099	19	21.4	0.39
Penoxsulam + cyhalofop 0.072	100	28.2	0.069	71	39.7	0.67
Penoxsulam + cyhalofop 0.108	88	28.4	0.075	54	40.6	0.64
LSD <sub>0.05</sub>	NS	4.8	0.070	16	13.2	0.54

Abbreviations: LSD<sub>0.05</sub>, least significant difference at 5% level of significance; NS, nonsignificant.

was statistically nonsignificant. Because of strong competition with corn, rice produced the lowest amount of biomass in the penoxsulam + cyhalofop treatment (**Table 1**). Although bispyribac completely controlled volunteer corn seedlings, rice did not produce highest biomass in this treatment. This response could be due to the phytotoxic effect of bispyribac on rice. In earlier studies in the Philippines and USA, bispyribac was reported to cause toxic effect on rice [9-11]. In the Philippines, for example, bispyribac reduced rice shoot biomass by up to 37% [9]. In another study, bispyribac at 0.03 kg·ha<sup>-1</sup> reduced rice biomass by 65% compared with a nontreated control [12]. Rice susceptibility to fenoxaprop has also been reported [13].

### 3.2. Field Experiment

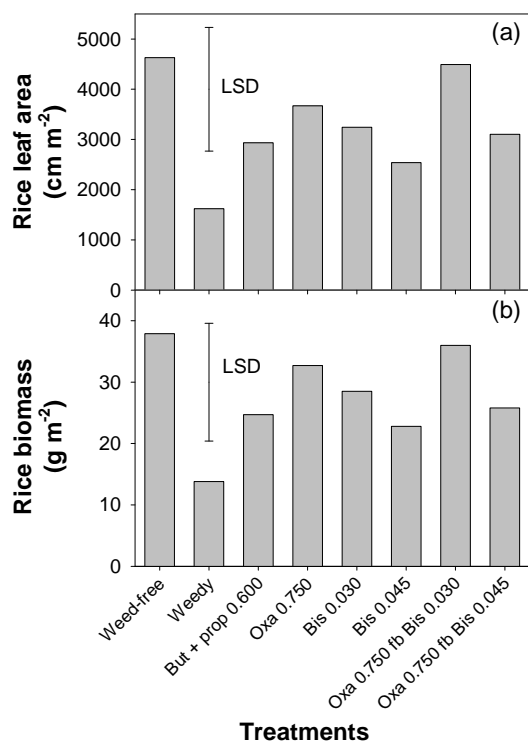

In the greenhouse experiment, fenoxaprop + ethoxysulfuron and penoxsulam + cyhalofop did not provide effective control of corn seedlings and therefore, these treatments were not included in the field experiment. Plots treated with a single application of pre-emergence herbicide (*i.e.*, oxadiazon) or treated with no herbicide had greater density and biomass of corn seedlings compared with other treatments (**Figure 1**). The application of early post-emergence (butachlor + propanil) or late post-emergence (bispyribac) herbicides reduced corn density compared with the nontreated control (weedy) (**Figure 1(a)**). Compared with the weedy plots, butachlor + propanil and bispyribac-treated plots produced fewer biomass of corn seedlings (**Figure 1(b)**). Compared with the weedy plots, sole application of bispyribac suppressed corn biomass by 60% - 82% and sequential application of oxadiazon and bispyribac suppressed corn biomass by 89% - 91%. Although the plots treated with the sequential application of oxadiazon and bispyribac (9 - 11 g·m<sup>-2</sup>) had lower

**Figure 1. Effect of weed control treatments [weedy (nontreated control); butachlor + propanil at 0.600 kg·ai·ha<sup>-1</sup>; oxadiazon at 0.75 kg·ai·ha<sup>-1</sup>; bispyribac at 0.030 and 0.045 kg ai ha<sup>-1</sup>; oxadiazon at 0.75 kg ai ha<sup>-1</sup> followed by bispyribac at 0.030 kg·ai·ha<sup>-1</sup>; and oxadiazon at 0.75 kg·ai·ha<sup>-1</sup> followed by bispyribac at 0.045 kg·ai·ha<sup>-1</sup>] on density (a) and biomass (b) of corn.**

corn biomass than the plots treated with bispyribac alone (17 - 37 g·m<sup>-2</sup>), the difference was statistically nonsignificant.

Rice produced highest leaf area (4600 cm<sup>2</sup>·m<sup>-2</sup>) and biomass (38 g·m<sup>-2</sup>) in the weed-free plots (**Figure 2**).

**Figure 2.** Effect of weed control treatments [weed-free (no corn was broadcast in this treatment; weedy (nontreated control); butachlor + propanil at  $0.600 \text{ kg ai ha}^{-1}$ ; oxadiazon at  $0.75 \text{ kg ai ha}^{-1}$ ; bispyribac at  $0.030$  and  $0.045 \text{ kg ai ha}^{-1}$ ; oxadiazon at  $0.75 \text{ kg ai ha}^{-1}$  followed by bispyribac at  $0.030 \text{ kg ai ha}^{-1}$ ; and oxadiazon at  $0.75 \text{ kg ai ha}^{-1}$  followed by bispyribac at  $0.045 \text{ kg ai ha}^{-1}$ ] on leaf area (a) and biomass (b) of rice.

The next best treatment was oxadiazon followed by bispyribac at  $0.03 \text{ kg ha}^{-1}$ , which produced a leaf area of  $4500 \text{ cm}^2 \cdot \text{m}^{-2}$  and biomass of  $36 \cdot \text{g} \cdot \text{m}^{-2}$ . Compared with the nontreated plots (weedy), the plots treated with oxadiazon followed by bispyribac at  $0.03 \text{ kg ha}^{-1}$  produced 2.8 times more leaf area and 2.6 times more rice biomass.

The results of our study suggest that volunteer corn seedlings can be managed by using bispyribac in dry-seeded rice systems. However, bispyribac may cause phytotoxic effect on some rice cultivars. In previous studies, rice toxicity due to bispyribac application has been reported [10]. However, there was little effect on grain yield of rice. Furthermore, bispyribac is widely used to manage weeds in direct-seeded rice systems in other countries, e.g., India and Sri Lanka [8,14,15]. Therefore, in the absence of other effective management strategies, bispyribac can be used to manage volunteer corn seedlings. In dry-seeded rice systems, weeds are the most important biological constraints as weeds emerge simultaneously with rice seedlings [4]. Therefore, there is a need to apply pre-emergence herbicides to achieve effective weed control. At present, a pre-emergence followed by one or two post-emergence herbicides are applied in

dry-seeded rice systems [7,16]. Our study also found that oxadiazon as pre-emergence and bispyribac as post-emergence can control volunteer corn seedlings. However, there is a need to integrate other control measures, such as the use of stale seedbed practice, to achieve complete control of corn seedlings in dry-seeded rice systems.

#### 4. Conclusion

Volunteer corn seedlings severely compete with rice crop in dry-seeded rice systems, in which there is no standing water. Bispyribac-sodium can be used to control such corn seedlings in rice. The sequential application of oxadiazon and bispyribac suppressed corn biomass by 90% as compared with the non-treated control.
